
AI-Powered Credit Risk Intelligence Platform

NeoStats AI Engineer Internship — Candidate Assignment

Home Credit Default Risk dataset (307,511 applicants, real Kaggle data) · EDA → ML → Explainability → Talk-to-Data → Docker

OBJECTIVE

What this platform does

- Predicts loan default probability for Home Credit applicants and converts it into a business-readable risk score and band (Low / Medium / High).
- Explains every prediction (SHAP) so a non-technical credit officer can see which factors drove the decision.
- Derives simple IF/THEN policy rules from the model, independent of the black-box score, for credit-policy review.
- Lets analysts ask plain-English questions about the applicant data and get validated-SQL-backed answers.
- Ships as a single Docker Compose service an evaluator can run with one command.

Why this matters to a bank

- Faster decisions: automated risk scoring removes manual underwriting bottlenecks for routine applications.
- Better decisions: ROC-AUC / PR-AUC and SHAP-driven review catch risk that simple rules miss.
- Explainable & auditable: every score comes with a feature-level reason — required for regulatory review.
- Accessible: business analysts explore the applicant book in plain English, no SQL required.
- Bridges ML and policy: the rules module turns model behavior into reviewable, adjustable credit-policy language.

Component overview

All four components run inside one container; data/ and models/ are host-mounted volumes, never baked into the image.

A deliberate scoping decision

- Home Credit ships 7 relational tables (bureau, previous applications, credit card balance, ...).
- This build works from `application_train.csv` — the applicant-level table — rather than joining all 7.
- Reasoning: `application_train` already carries demographics, income, credit terms, and several bureau-derived `EXT_SOURCE` scores; a full multi-table join is a multi-day feature-engineering project on its own and raises real risk of an unreliable pipeline within this assignment's time-box.
- Trade-off is explicit here and in the README — with more time, joining `bureau.csv` (credit-bureau history) would likely add the single highest-value signal.

Dataset summary: the real Home Credit data

Business insight 1 & 2: income type and education

Maternity leave and Unemployed applicants show the highest default rates by income type; default rate falls steadily as education level rises.

Business insight 3 & 4: income and credit-to-income ratio

Defaulters skew toward lower income and a higher credit-to-income ratio — both engineered as first-class model features (AMT_INCOME_TOTAL, CREDIT_INCOME_RATIO).

Business insight 5: applicant age, and the raw data

5. Applicant age distribution

Raw sample data

	SK_ID_CURR	TARGET	NAME_CONTRACT_TYPE	CODE_GENDER	FLAG_OWN_CAR	FLAG_OWN_REALTY	CNT_CHILDREN	AMT_INCOME_TOTAL	AMT_CREDIT	AMT_ANNUITY	AMT_GOODS_PRICE	NAME_TYPE_SUITE	NAME_INCOME_TYPE	NAME_EDUCATION_TYPE
0	100002	1	Cash loans	M	N	Y	0	202500	406597.5	24700.5	351000	Unaccompanied	Working	Secondary / secondary s
1	100003	0	Cash loans	F	N	N	0	270000	1293502.5	35698.5	1129500	Family	State servant	Higher education
2	100004	0	Revolving loans	M	Y	Y	0	67500	135000	6750	135000	Unaccompanied	Working	Secondary / secondary s
3	100006	0	Cash loans	F	N	Y	0	135000	312682.5	29686.5	297000	Unaccompanied	Working	Secondary / secondary s
4	100007	0	Cash loans	M	N	Y	0	121500	513000	21865.5	513000	Unaccompanied	Working	Secondary / secondary s
5	100008	0	Cash loans	M	N	Y	0	99000	490495.5	27517.5	454500	Spouse, partner	State servant	Secondary / secondary s
6	100009	0	Cash loans	F	Y	Y	1	171000	1560726	41301	1395000	Unaccompanied	Commercial associate	Higher education
7	100010	0	Cash loans	M	Y	Y	0	360000	1530000	42075	1530000	Unaccompanied	State servant	Higher education

Applicant volume peaks around age 35-40 and tapers at both ends; the app also exposes the raw sample table for direct inspection.

Model design & imbalance strategy

- Model: LightGBM (LGBMClassifier) — handles mixed numeric/categorical features natively, trains in under a minute on the full 307,511-row dataset, and gives exact SHAP TreeExplainer support for Part 4.
- Imbalance handling: `scale_pos_weight` (cost-sensitive weighting), not SMOTE. Synthetic oversampling on high-dimensional tabular data tends to fabricate unrealistic applicant profiles without a reliable AUC gain — weighting keeps every training row real.
- Feature engineering: `CREDIT_INCOME_RATIO`, `ANNUITY_INCOME_RATIO`, `CREDIT_TERM`, `AGE_YEARS`, `YEARS_EMPLOYED`, `EMPLOYED_AGE_RATIO` — chosen to stay analyst-readable for the explainability and rules layers.
- Risk bands are calibrated as percentiles of the model's own validation output (bottom 60% = Low, next 30% = Medium, top 10% = High) rather than fixed probability cutoffs — `scale_pos_weight` training inflates raw probabilities, so relative score tiers give a reliable, well-populated Low/Medium/High split.

Model performance (validation set)

ROC-AUC	PR-AUC	Recall (defaulters)	Precision (defaulters)
0.7689	0.2568	0.6731	0.1771

- ROC-AUC 0.7689 — solid separation between defaulters and repayers, in line with typical single-table Home Credit solutions.
- Recall (defaulters) 0.6731 — the model catches roughly two-thirds of actual defaulters.
- Precision (defaulters) 0.1771 reflects the 8% base rate: at any reasonable recall, most flagged applicants are false positives — expected and why risk banding (not a single yes/no) is the right output shape for this use case.

ROC-AUC and PR-AUC are the headline metrics (not accuracy) — with an 8.1% default rate, a model predicting “no default” for everyone would score >90% accuracy while being useless.

SHAP: what drives risk across the portfolio

Global importance computed live over a 200-applicant sample from the real dataset.

- EXT_SOURCE_2 and EXT_SOURCE_3 (bureau-derived credit scores) dominate — consistent with published Home Credit analyses.
- CREDIT_TERM (annuity/credit ratio) and EXT_SOURCE_1 are the next strongest signals.
- SHAP TreeExplainer chosen over LIME: exact for tree ensembles, fast enough for live per-applicant explanations in the UI.

Data-driven risk-band thresholds (percentiles of the model's own score distribution) reliably produce all three tiers — not just Medium/High — across real applicants from the dataset.

From black-box score to reviewable policy

Credit Risk Intelligence Platform

Home Credit Default Risk — EDA, ML scoring, explainability, business rules, and a talk-to-data chatbot.

EDA Risk Prediction Explainability **Business Rules** Talk to Data

Business-readable decision rules

A shallow surrogate decision tree trained to mimic the model's decision boundary — reviewable by a credit policy team, independent of the black-box model score.

Rule tree depth (more depth = more, narrower rules)

3

Derive rules

- Rule 1** — IF $\text{EXT_SOURCE_3} \leq 0.31$ AND $\text{EXT_SOURCE_2} \leq 0.38$ AND $\text{EXT_SOURCE_3} \leq 0.15$ → High risk (covers 1.14% of applicants, 34.13% observed default rate)
- Rule 2** — IF $\text{EXT_SOURCE_3} \leq 0.31$ AND $\text{EXT_SOURCE_2} \leq 0.38$ AND $\text{EXT_SOURCE_3} > 0.15$ → Medium risk (covers 3.02% of applicants, 23.13% observed default rate)
- Rule 3** — IF $\text{EXT_SOURCE_3} \leq 0.31$ AND $\text{EXT_SOURCE_2} > 0.38$ AND $\text{EXT_SOURCE_3} \leq 0.14$ → Medium risk (covers 2.26% of applicants, 19.62% observed default rate)
- Rule 4** — IF $\text{EXT_SOURCE_3} > 0.31$ AND $\text{EXT_SOURCE_2} \leq 0.39$ AND $\text{EXT_SOURCE_3} \leq 0.54$ → Medium risk (covers 12.03% of applicants, 14.86% observed default rate)
- Rule 5** — IF $\text{EXT_SOURCE_3} \leq 0.31$ AND $\text{EXT_SOURCE_2} > 0.38$ AND $\text{EXT_SOURCE_3} > 0.14$ → Medium risk (covers 8.2% of applicants, 11.52% observed default rate)
- Rule 6** — IF $\text{EXT_SOURCE_3} > 0.31$ AND $\text{EXT_SOURCE_2} \leq 0.39$ AND $\text{EXT_SOURCE_3} > 0.54$ → Low risk (covers 8.39% of applicants, 7.66% observed default rate)
- Rule 7** — IF $\text{EXT_SOURCE_3} > 0.31$ AND $\text{EXT_SOURCE_2} > 0.39$ AND $\text{EXT_SOURCE_3} \leq 0.54$ → Low risk (covers 33.46% of applicants, 6.38% observed default rate)
- Rule 8** — IF $\text{EXT_SOURCE_3} > 0.31$ AND $\text{EXT_SOURCE_2} > 0.39$ AND $\text{EXT_SOURCE_3} > 0.54$ → Low risk (covers 31.5% of applicants, 3.27% observed default rate)

- Approach: a shallow surrogate decision tree mimics the production model's decision boundary in plain IF/THEN language a credit-policy team can review directly.
- Rule 1 (highest risk): $\text{EXT_SOURCE_3} \leq 0.31$ AND $\text{EXT_SOURCE_2} \leq 0.38$ AND $\text{EXT_SOURCE_3} \leq 0.15$ → 34.13% observed default rate.
- Rule 8 (lowest risk): $\text{EXT_SOURCE_3} > 0.31$ AND $\text{EXT_SOURCE_2} > 0.39$ AND $\text{EXT_SOURCE_3} > 0.54$ → 3.27% observed default rate, covering 31.5% of applicants.

All 8 rules derived live from the real dataset (depth-3 surrogate tree) — EXT_SOURCE_2 and EXT_SOURCE_3 anchor every split, matching the SHAP global-importance ranking.

Natural language, validated SQL, real answers

Credit Risk Intelligence Platform

Home Credit Default Risk — EDA, ML scoring, explainability, business rules, and a talk-to-data chatbot.

EDA Risk Prediction Explainability Business Rules Talk to Data

Ask questions about the applicant data

Try: "What is the average income of applicants who defaulted?" - "How many applicants are high-risk vs low risk by education level?" - "Compare average annuity amount between genders"

Compare average annuity amount between genders.

Male applicants have an average annuity amount of 32,224.46 across 1,863 applications. In comparison, female applicants have an average annuity amount of 30,054.25 across 1,937 applications. This shows that while there are significantly more female applicants in the dataset, male applicants average a higher annuity amount.

SQL used

SELECT gender, AVG(annuity_amount) AS avg_annuity, COUNT(*) AS n FROM applications_readable GROUP BY gender LIMIT 10

Result data

	gender	avg_annuity	n
0	F	30054.253	1937
1	M	32224.4621	1863

What is the average income of applicants who defaulted?

The average annual income for applicants who defaulted on their loans is \$81,088.36. This figure is calculated across all records in our application database where a loan default was recorded.

SQL used

SELECT AVG(annual_income) AS avg_income_defaulters FROM applications_readable WHERE defaulted = 1

Result data

	avg_income_defaulters
0	81088.3579

- “Compare average annuity between genders” → correct SQL, correct grouped result, grounded plain-English answer.
- “Average income of applicants who defaulted” → \$81,088.36, computed directly from the real data, not estimated.
- SQL safety: SELECT-only, single-statement, allow-listed tables, forbidden-keyword check, automatic LIMIT — verified against DROP/UPDATE/multi-statement attempts.

Two real exchanges against the full 307,511-row dataset, powered by Gemini (free tier) — SQL is shown and validated before execution, and every number in the answer comes from the actual query result.

Prompt engineering, token optimization & provider flexibility

- Two-stage LLM flow: question → SQL (validated before execution) → real query results → plain-English answer. The answer stage only ever sees data that actually came back from SQLite — it cannot invent numbers.
- Schema exposed to the LLM is a trimmed, business-readable view (13 columns) rather than the raw 122-column table — the core token-optimization decision.
- Multi-provider by design: Anthropic, OpenAI, or Gemini (free tier, no billing) — swap providers via one .env variable, no code change.
- Gemini-specific hardening: automatic detection and one-retry-with-larger-budget when a response is truncated mid-generation (finish_reason=MAX_TOKENS), so a tight token budget never silently returns a broken SQL query or a cut-off answer.
- Conversation memory: the last 4 turns are passed back to the LLM so follow-up questions resolve correctly, without unbounded token growth.

Docker deployment, limitations, and next steps

- `docker-compose up --build` builds the single Streamlit service, mounts `./data` and `./models` as volumes (dataset and model artifacts are never baked into the image or committed to git), and exposes the app on `:8501` — verified working end-to-end on the full real dataset.
- Startup is self-diagnosing: the UI detects a missing dataset or an untrained model and tells the evaluator exactly what to do, with a one-click “Train model” fallback in-app.
- Known limitations: scoped to the applicant-level table only (see slide 5); raw model probabilities are uncalibrated due to `scale_pos_weight` training, addressed via percentile-based risk bands rather than a separate calibration model.
- Next steps with more time: join `bureau.csv` / `previous_application.csv` for stronger signal; add proper probability calibration (`CalibratedClassifierCV`); cache SHAP results; add authentication in front of the chatbot.
